

# AIG150- Week 2

## **Working With Real Data**

### **Reading Text:**

Chap 04, 06: Pandas for everyone

Chap 06: Python for Data Science for Dummies

# Agenda

- Importing and exporting data
  - Streaming, and Sampling Data
  - Accessing Data in Structured Flat-File Form
  - Sending Data in unstructured File Form
  - Managing Data from Relational Databases
  - Accessing Data from the Web
- Data Cleaning
- Data Assembly
  - Tidy data
  - Concatenation
  - Merging multiple datasets

# Streaming, and Sampling Data

- Most efficient method to work with data is to load it directly in memory
- Reading the whole file at once and load it in memory using `file.read()`, not for larger files
- Streaming: Download individual pieces to avoid delays. Read observations one by one
- Sampling: Retrieve selected records

# Accessing Data in Structured Flat-File Form

—Text file

—Csv file

—Excel file

# Sending Data in Unstructured File Form

- ↪ No fixed structure like a csv or excel file where data is organized in rows and columns
- ↪ Contains a series of bits
- ↪ Need an interpretation algorithm to extract information
- ↪ File header contains hints on the type of data
- ↪ Examples are images, audio and video files

# Managing Data from Databases

- ↪ Relation databases such as SQL, PostgreSQL, Oracle and so on
- ↪ To read data from a table, we use the `read_sql_table()` method
- ↪ `create_engine()` method is used to create an engine from a database URI
- ↪ NoSQL databases such as MongoDB
- ↪ Use [pyMongo](#) to work with MongoDB

# Accessing Data from the Web

- ↪ Data collected from web services and microservices
- ↪ XML and JSON

# What is Tidy Data ?

- ↗ Each row is an observation
- ↗ Each column is a variable
- ↗ Each type of observational unit forms a table

# What is Tidy Data ?

- ↪ Each row is an observation
- ↪ Each column is a variable
- ↪ Each type of observational unit forms a table
- ↪ These 3 are interrelated rules, all must be satisfied for a tidy data

# Which One Is Tidy ????

*Table 1*

| Country     | Year | Cases | Population |
|-------------|------|-------|------------|
| Afghanistan | 1999 | 745   | 19987071   |
| Afghanistan | 2000 | 2666  | 20595360   |
| Brazil      | 1999 | 37737 | 172006362  |
| Brazil      | 2000 | 80488 | 174504898  |

*Table 2*

| Country     | Year | type       | count     |
|-------------|------|------------|-----------|
| Afghanistan | 1999 | population | 19987071  |
| Afghanistan | 2000 | cases      | 745       |
| Brazil      | 1999 | cases      | 37737     |
| Brazil      | 2000 | population | 174504898 |

## Same data spread across two tables

| Country     | 1999  | 2000  |
|-------------|-------|-------|
| Afghanistan | 745   | 266   |
| Brazil      | 37737 | 80488 |

| Country     | 1999      | 2000      |
|-------------|-----------|-----------|
| Afghanistan | 19987071  | 20595360  |
| Brazil      | 172006362 | 174504898 |

# How To Tidy Data Using Python

- melt()** unpivots a DataFrame from wide to long format
- Pivot()** reshapes DataFrame organized by given index/ column values
- See the sample code provided with the lecture

# Merging Multiple Datasets

Identify:

- What needs to be combined ?
  - Do we need to concatenate or join the data ?
  - The appropriate function for merging data sets
  - Assess if the merge was proper
- See the sample code provided with the lecture
